## 9 Summary

10 EnsembleKalmanProcesses.jl is a Julia-based toolbox that can be used for a broad class of  
11 black-box gradient-free optimization problems. Specifically, the tools enable the optimization,  
12 or calibration, of parameters within a computer model in order to best match user-defined  
13 outputs of the model with available observed data ([Kennedy & O'Hagan, 2001](#)). Some of the  
14 tools can also approximately quantify parametric uncertainty ([Huang, Huang, et al., 2022](#)).  
15 Though the package is written in Julia, a read-write TOML-file interface is provided so that  
16 the tools can be applied to computer models implemented in any language. Furthermore, the  
17 calibration tools are non-intrusive, relying only on the ability of users to compute an output of  
18 their model given a parameter value.

19 As the package name suggests, the tools are inspired by the well-established class of ensemble  
Kalman methods. Ensemble Kalman filters are currently one of the only practical ways to  
21 assimilate large volumes of observational data into models for operational weather forecasting  
22 ([Evensen, 1994](#); [Houtekamer & Mitchell, 1998, 2001](#)). In the data assimilation setting, a  
23 computational weather model is integrated for a short time over a collection, or ensemble,  
24 of initial conditions, and the ensemble is updated frequently by a variety of atmospheric  
25 observations, allowing the forecasts to keep track of the real system.

26 The workflow is similar for ensemble Kalman processes. Here, a computer code is run (in  
27 parallel) for an ensemble of different values of the parameters that require calibration, producing  
28 an ensemble of outputs. This ensemble of outputs is then compared to observed data, and  
29 the parameters are updated to a new set of values which reduce the output-data misfit. The  
30 computer model is then evaluated for the new ensemble values and the outputs. Optimality of  
31 the update is guaranteed for linear models and Gaussian uncertainties, but good performance  
32 is observed outside of these settings, see ([Schillings & Stuart, 2017](#)). The process is iterated  
33 until a user-defined criterion of convergence is met. Optimal values are selected from statistics  
34 of the final ensemble.

## 35 Statement of need

36 The task of estimating parameters of a computer model or simulator such that its outputs  
37 fit with data is ubiquitous in science and engineering, coming under many names such as  
38 calibration, inverse problems, and parameter estimation. In statistics and machine learning,  
39 when closed-form estimators of parameters of a model are unavailable, similar approaches may  
40 need to be employed to fit the model to data. There is a wide variety of algorithms to suit

41 these applications; however, there are many bottlenecks in the practical application of such  
42 methods to computer codes:

- 43     ▪ Legacy codes: Often code is old, and written in different languages than the packages  
44         implementing the calibration algorithms, requiring elaborate interfaces.
- 45     ▪ Complex codes: Often large complex codes are difficult to change, so application of  
46         intrusive calibration tools to models can be challenging.
- 47     ▪ Derivatives: When derivatives of a model output can be taken with respect to parameters,  
48         they can often improve the rate of convergence. But in many practical cases, these  
49         parameter-to-output maps are not differentiable; they may be chaotic or stochastic. Here  
50         one should not – or cannot – apply gradient-based methods.
- 51     ▪ Lack of parallelism: There is now widespread access to high-performance computing  
52         clusters, cloud computing, and local multi-threading, and such facilities should be  
53         exploited where possible.

54 `EnsembleKalmanProcesses.jl` aims to provide a flexible and comprehensive solution to address  
55 these challenges:

- 56     1. It is embarrassingly parallel with respect to the ensemble; therefore, all computer model  
57         evaluations within an ensemble can happen simultaneously within an iteration.
- 58     2. It is derivative-free, and so is appropriate for computer codes for which derivatives are  
59         not available. The optimal updates are robust to noise.
- 60     3. It is non-intrusive and so can be applied to black-box computer codes written in any  
61         language or style, or to computer models for which the source code is not available to  
62         the user.
- 63     4. With scalability enhancements, such as the ones provided by the `Localizer` structure, it  
64         can be applied to high-dimensional problems.

## 65 **State of the field**

66 Many gradient-based optimizers have been implemented in Julia, collected in `Optim.jl` and  
67 `JuliaSmoothOptimizers.jl`, for example. Some gradient-free optimization tools, better  
68 suited for non-deterministic or noisy optimization are collected within packages such as  
69 `BlackBoxOptim.jl` and `Metaheuristics.jl`. Although these packages feature a number of  
70 ensemble-based approaches, none utilize Kalman-based statistical updates of ensembles, and  
71 instead rely on heuristic algorithms inspired from biological processes such as natural selection  
72 (genetic algorithm) or swarming (particle swarm optimization). A related class of methods  
73 to calibrate black-box computer codes are based on Bayesian inference, such as (Markov  
74 Chain) Monte Carlo, implemented in `Turing.jl`, for example. Such methods are effective but  
75 are far more computationally expensive as they provide an entire joint distribution for model  
76 parameters, from which the optimum is taken as the summary statistic.

77 An ensemble Kalman filter is implemented in `EnKF.jl`, but the use case is state estimation  
78 from sequential data, rather than applied to model parameter estimation independent of the  
79 state. Kalman filters without ensemble approximation are also available in `Kalman.jl` and  
80 `GaussianFilters.jl`.

81 `EnsembleKalmanProcesses.jl` fills the need for more computationally inexpensive, gradient-  
82 free, mathematically-grounded ensemble approaches for calibration that are provably optimal  
83 in simple settings, and have a large literature of extensions to complex problems.

## 84 Features

85 There are different ensemble Kalman algorithms in the literature, which differ in the way that  
86 the ensemble update is performed. The following ensemble Kalman processes are implemented  
87 tools in our package, and we provide published references for detailed descriptions and evidence  
88 of their efficacy:

- 89     ▪ Ensemble Kalman Inversion (EKI, Iglesias et al. (2013)),
- 90     ▪ Ensemble Kalman Sampler (EKS, Garbuno-Inigo, Hoffmann, et al. (2020); Garbuno-Inigo,  
91       Nüsken, et al. (2020)),
- 92     ▪ Unscented Kalman Inversion (UKI, Huang, Schneider, et al. (2022)),
- 93     ▪ Sparse Ensemble Kalman Inversion (SEKI, Schneider, Stuart, et al. (2022)).

94 We also implement some features to improve robustness and flexibility of the ensemble  
95 algorithms:

- 96     ▪ The `ParameterDistribution` structure allows us to perform calibrations for parameters  
97       with known constraints. It does so by defining transformation maps under-the-hood from  
98       the constrained space to an unconstrained space where the optimization problem can be  
99       suitably defined. Constrained optimization using this framework has been successfully  
100       demonstrated in a variety of settings (Dunbar et al., 2022; Lopez-Gomez et al., 2022;  
101       Schneider, Dunbar, et al., 2022).
- 102     ▪ The `FailureHandler` structure allows calibrations to continue when several ensemble  
103       members fail. Common reasons for failure could be, for instance, simulation blow-up for  
104       certain parameter configurations, user termination of slow computations, data corruption,  
105       or bad nodes in a high-performance computing facility. This methodology is demonstrated  
106       in Lopez-Gomez et al. (2022).
- 107     ▪ The `Localizer` structure allows us to overcome the restriction of the solution of the  
108       calibration to the linear span of the initial ensemble, and to reduce sampling errors  
109       due to the finite size of the ensemble. Various such localization and sampling error  
110       correction methods are implemented in `EnsembleKalmanProcesses.jl` (Lee, 2021; Tong  
111       & Morzfeld, 2022).
- 112     ▪ The TOML-file interface defined in the `UQParameters` module allows non-intrusive use  
113       of `EnsembleKalmanProcesses.jl` through TOML files, which are widely used for config-  
114       uration files and easily read in any programming language. Given the computer model  
115       to calibrate and prior distributions on the parameters, `EnsembleKalmanProcesses.jl`  
116       reads these distributions from a file and, after an iteration of the ensemble Kalman  
117       algorithm, writes each member of the updated ensemble to a parameter file. Each  
118       of these parameter files can be then read individually to initiate the ensemble of the  
119       computer model for the next iteration.

## 120 Pedagogical example

121 In this example, the computer code simulates a sine curve

$$f(A, v) = A \sin(t + \varphi) + v, \quad \forall t \in [0, 2\pi],$$

122 with a random phase shift  $\varphi$  applied to every evaluation. We define the observable map

$$G(A, v) = [\max f(A, v) - \min f(A, v), \text{mean} f(A, v)].$$

123 We treat  $\varphi$  as a “nuisance parameter” that we are not interested in estimating, thus the  
124 observable map  $G(A, v)$  is chosen independent of  $\varphi$  so that it will not pollute the results of  
125 the calibration.

126 We are given one sample measurement of  $G$ , polluted by Gaussian noise  $\mathcal{N}(0, \Gamma)$ , and call  
 127 this  $y$ . Our task is to deduce the most likely amplitude  $A$  and vertical shift  $v$  of the curve that  
 128 produced the  $y$ .

129 We encode information into prior distributions over the parameters:

```
# A is positive, has likely value 2 with standard deviation 1
# v has likely value 0 with standard deviation 5
prior_A = constrained_gaussian("amplitude", 2, 1, 0, Inf)
prior_v = constrained_gaussian("vert_shift", 0, 5, -Inf, Inf)
prior = combine_distributions([prior_A, prior_v])
```

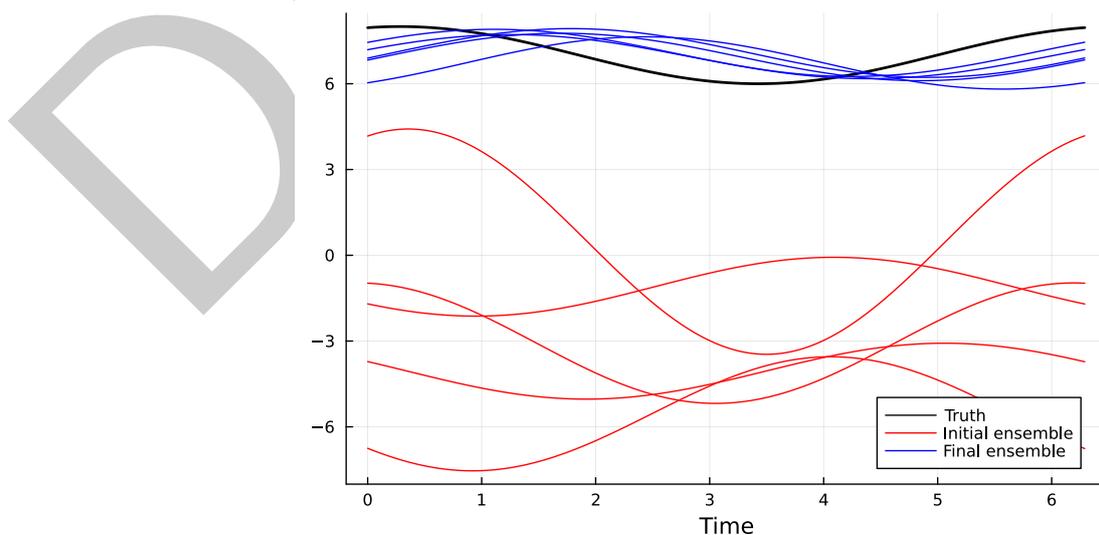

130 To use a basic ensemble method we need to specify one more hyperparameter, the size of  
 131 the ensemble, which we take to be  $N_{\text{ensemble}} = 5$ . We now begin solving the problem, by  
 132 creating the initial ensemble from our prior, and selecting the `Inversion()` tool to perform  
 133 ensemble Kalman inversion:

```
initial_ensemble = construct_initial_ensemble(prior, N_ensemble)
ensemble_kalman_inversion = EnsembleKalmanProcess(initial_ensemble, y,  $\Gamma$ , Inversion())
```

134 Then we iterate...

```
N_iterations = 5
for i in 1:N_iterations
    # get the latest parameter ensemble
    params_i = get_phi_final(prior, ensemble_kalman_process)
    # run a simulation for each parameter in the ensemble
    G_ens = hcat([G(params_i[:, i]) for i in 1:N_ensemble]...)
    # perform the Kalman update, producing a new ensemble
    update_ensemble!(ensemble_kalman_process, G_ens)
end
```

135 We show the initial and final ensemble in Figure 1, by evaluating  $f$  at these parameters. We  
 136 observe that, the final sinusoid ensemble has greatly reduced the error in amplitude and vertical  
 137 shift to the truth, despite the presence of the random phase shifts.

**Figure 1:** Sinusoids produced from initial and final ensembles, and the sine curve that generated the data.

138 This final ensemble determines the problem solution; for ensemble Kalman inversion, a best  
139 estimate of the parameters is taken as the mean of this final ensemble:

```
best_parameter_estimate = get_phi_mean_final(prior, ensemble_kalman_process)
```

140 The Julia code and further explanation of this example is provided in the documentation.

## 141 Research projects using the package

- 142 ■ EnsembleKalmanProcesses.jl has been used to train physics-based and machine-learning  
143 models of atmospheric turbulence and convection, implemented using Flux.jl and  
144 TurbulenceConvection.jl (Lopez-Gomez et al., 2022). In this application, the available  
145 model outputs are not differentiable with respect to the learnable parameters, so gradient-  
146 based optimization was not an option. In addition, the unscented Kalman inversion  
147 algorithm was used to approximately quantify parameter uncertainty.
- 148 ■ EnsembleKalmanProcesses.jl features within Calibrate-Emulate-Sample (CES, Cleary  
149 et al. (2021)), a pipeline used to accelerate parameter uncertainty quantification (by a  
150 factor of  $10^3 - 10^4$  with respect to Monte Carlo methods) by using statistical emulators.  
151 EnsembleKalmanProcesses.jl is used to choose training points for these emulators.  
152 The training points are naturally concentrated by the ensemble Kalman processes into  
153 areas of high posterior probability mass. Within CES, the trained emulators are used to  
154 sample this probability distribution, and by design are most accurate where they need to  
155 be. CES has been successfully used to quantify parameter uncertainty within the moist  
156 convection scheme of a simplified climate model (Dunbar et al., 2021, 2022; Howland et  
157 al., 2022), within a droplet collision-coalescence scheme for cloud microphysics (Bieli et  
158 al., 2022), and within boundary layer turbulence schemes for ocean modeling (Hillier,  
159 2022).
- 160 ■ EnsembleKalmanProcesses.jl has been used to learn hyperparameters within a machine  
161 learning tool known as Random Features within a julia package RandomFeatures.jl.  
162 Here, the hyperparameters characterize an infinite family of functions, from which a  
163 finite sample is drawn to use as a basis in regression problems. The objective for learning  
164 the parameters is noisy and non-differentiable due to the random sampling, so ensemble  
165 Kalman processes naturally perform well in this setting.

## 166 Acknowledgements

167 We acknowledge contributions from several others who played a role in the evolution of this  
168 package. These include Jake Bolewski, Navid Constantinou, Gregory L. Wagner, Thomas  
169 Jackson, Michael Howland, Melanie Bieli, and Adeline Hillier. The development of this package  
170 was supported by the generosity of Eric and Wendy Schmidt by recommendation of the  
171 Schmidt Futures program, and by the Defense Advanced Research Projects Agency (Agreement  
172 No. HR00112290030).
